The continuing trend of higher printing resolutions has created the need for printing systems to be capable of printing ever faster and higher resolution. In addition, the consumer market for digital cameras has exploded to the point that one may now purchase digital cameras which include high-resolution CCD imaging devices capable of printing images with higher and higher resolutions. As the resolution increases, so too do the demands on the printer. Printing systems typically include a scanning component which must be capable of sening the high resolution images onto the print media and printing the image on the print media at a desired resolution. One common resolution is 300 dots per inch (dpi) and more recently, 600 dpi. However, current printing systems are limited in their ability to print high-resolution images due to the cost, speed, and accuracy of the components required to produce these high-resolution images. One of the ways that the need for higher resolution has been met in the printing market has been through the introduction of single pass printing systems. Generally, a single pass printing system consists of a raster output scanner (ROS) which is used to scan a video signal, an optical path, and a plurality of laser print heads. The video signal is scanned onto the optical path which serves to scan the video signal onto each of the plurality of laser print heads. Each of the laser print heads then correspond to a different pixel position on th
